

Blind Validation Study 02 — Statistical Claims

This synthetic report is intentionally designed to stress-test claim extraction, subgroup/timepoint mapping, statistical-method selection, interpretation, and reproducibility.

1. Subgroup and timepoint claim

At week 12, the Treatment group among Female participants had a mean change score of 9.4%.

2. Between-group inference

At week 12, the Treatment and Control groups showed a statistically significant difference in change score (Welch t-test, $p = 0.032$).

3. Association claim

Age was positively correlated with satisfaction rate (Pearson $r = 0.42$, $p = 0.010$).

4. Regression claim

Logistic regression indicated that age was associated with responder status with an odds ratio of 1.20.

5. Broad conclusion

The treatment was effective in all subgroups and at all timepoints.

6. Table-only summary

Metric	Reported value
Treatment mean change	5.5
Control mean change	2.4
Female Treatment mean change	9.4

All values should be independently reproduced from the supplied participant-level CSV.
